Molecular cloning and characterization of genes encoding FK506-binding proteins (FKBPs) in wheat (*Triticum aestivum* L.)

Abstract The family of FK506-binding proteins (FKBPs) consists of several members, which show peptidyl prolyl *cis-trans* isomerase (PPIase) activity. PPIases facilitate the conversion of peptidyl prolyl bonds from *cis* to *trans* conformation, a rate-limiting step in protein folding. In the present study, we carried out cloning of cDNAs encoding three different wheat FKBPs viz., TaFKBP20-1, TaFKBP16-1 and TaFKBP15-1. *In silico* analysis suggested their likely localization to nucleus, cytosol and endoplasmic reticulum, respectively. Biochemical analysis demonstrated that none of the three purified FKBP protein possesses detectable PPIase activity. Several positive interacting partners of TaFKBP20-1, TaFKBP16-1 and TaFKBP15-1 were identified using online software tools. The results of this study provide further evidence that PPIase activity in plant FKBPs is not conserved, and these proteins may be playing important roles in the cell through interaction with target proteins.

Electronic supplementary material The online version of this article (doi:10.1007/s13262-017-0438-8) contains supplementary material, which is available to authorized users.

Introduction

In vitro experiments have demonstrated that isomerization around proline peptide (Xaa-Pro) bond is one of the slow, rate limiting steps in folding of many proteins. The process of *cis-trans* isomerization of Xaa-Pro bond is accelerated by peptidyl prolyl *cis-trans* isomerases (PPIases) (Fischer et al. 1984). PPIases are ubiquitous in nature and are localized in the cytosol (Chou and Claver 1997), endoplasmic reticulum (ER) (Wu et al. 2005), and mitochondria and chloroplasts (Bociman et al. 1992) in the cell. PPIases comprise of three distinct classes of proteins—chaperonins and FK506-binding proteins (FKBPs), that bind to immunosuppressive drugs cyclosporin A (Halevy and Fischer et al. 1984), and FK506 and rapamycin (Hasting et al.
